

# Dementia prevention: What do we know and where do we go from here?

Never Stand Still

Science

Psychology

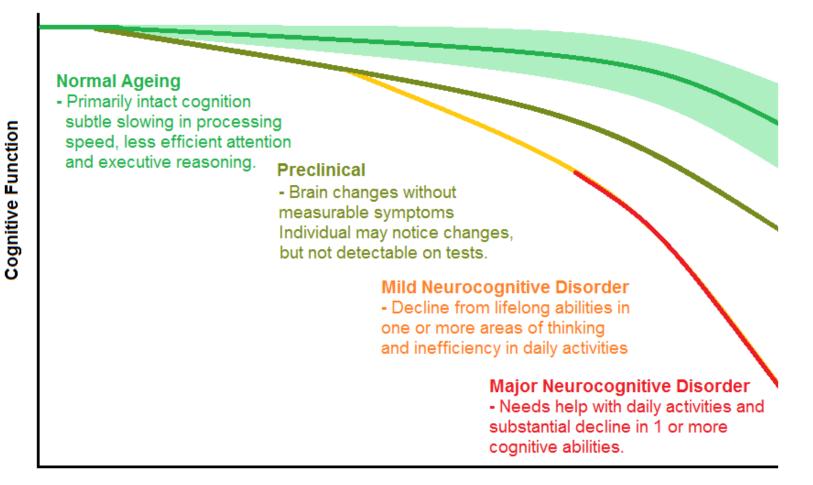

## Kaarin J. Anstey and Ruth Peters

## What is the problem?

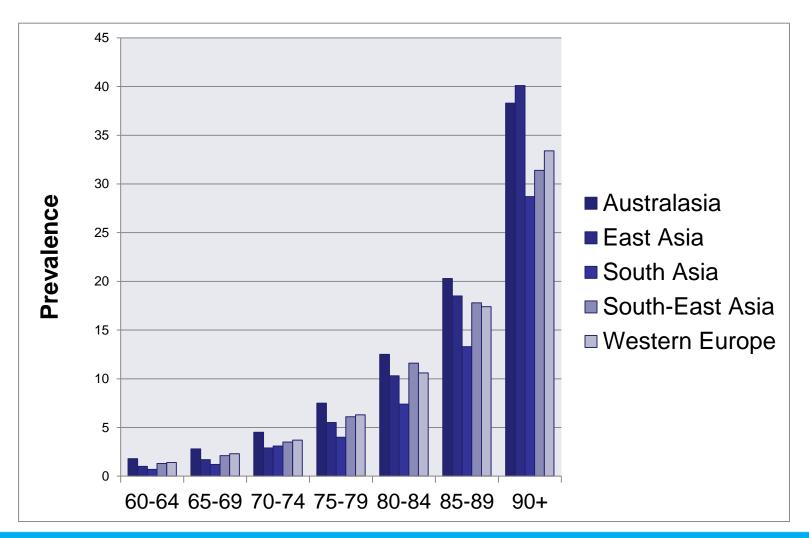

Time (Years)

## Size of the problem by age

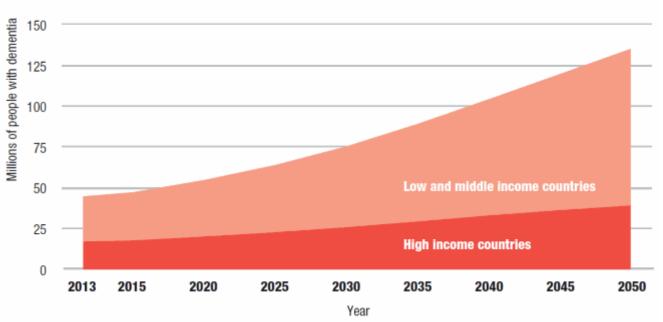

## Size of problem by numbers

Worldwide prevalence > 65 is 5-7% Estimated at 50 million living with dementia by 2017 75 Million expected by 2030 More prevalent in women, particularly at older ages Increasing due to demographic change

#### Number of people with dementia in low and middle income countries compared to high income countries

## What do we mean by 'Prevention'?

### **Primary Prevention**

Preventing disease or injury before it occurs – e.g. through vaccination, or removing exposure to risk factors – population level

### **Secondary Prevention**

Reduce impact of disease that has already occurred, or stop progress of those with preclinical disease (e.g. MCI) – either population or patient level

## **Tertiary Prevention**

Reduce impact and or slow rate of progression of established disease – patient level

Responsible: Who? How? Why?

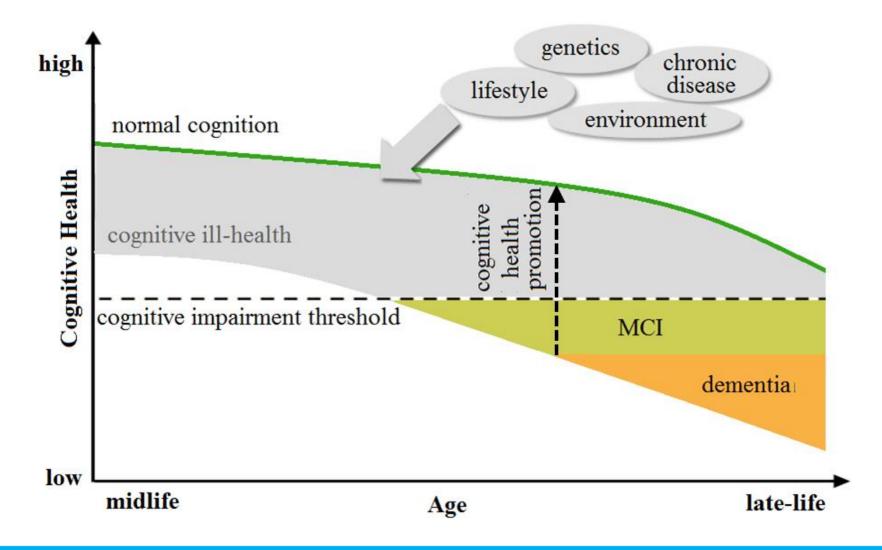

# What do we know now?

## A life course approach is required

## **Risk factors may be modifiable or non-modifiable**

Non-modifiable – genetics, country of birth, gender, age

Modifiable – lifestyle, clinical, environmental

## **Physical activity**

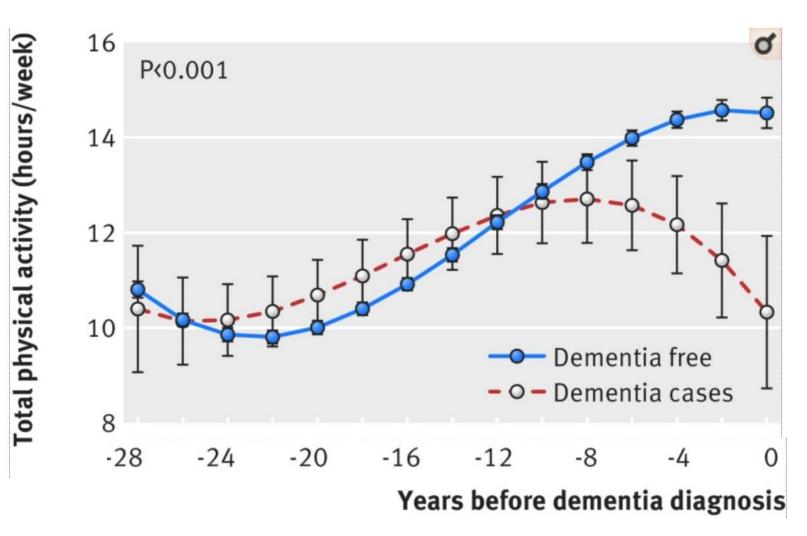

Adhering to international PA guidelines, (150 min/wk of MVPA, or brisk walk for 20-30 minutes most days) during the previous approximately 5 + years Has 40% reduced risk of AD.

Sample size	OR (95% CI)	Weight(%)	P value

Santoz-Lozano et al, 2016 Mayo Clinic Proceedings

## **Exercise and risk of dementia**

#### Whitehall study

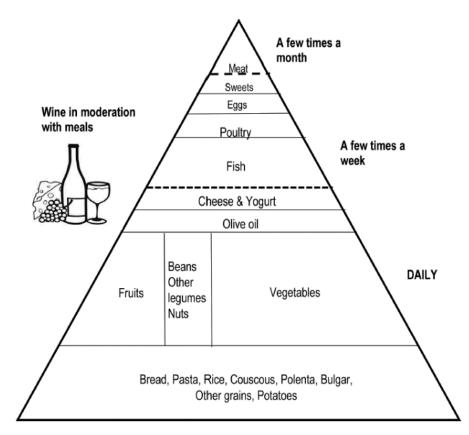

Physical activity no different at baseline Activity reduced prior to dementia Association may be due to reverse causality!

Sabia, Dugravot, Dartigues, Abell, Ebaz, Kivimaki, Singh-Manoux, BMJ, 2017

## **Mediterranean diet**

- Meta-analysis: 33% reduced risk of MCI or AD over 2-8 years (Singh et al 2014).
- DASH diet (Dietary Approaches to Stop Hypertension) protective against cognitive decline (e.g., Tangney et al 2014).

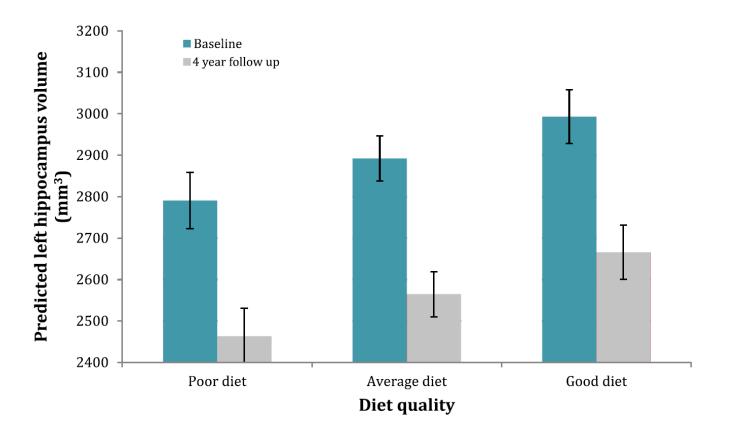

## Western diet and brain

## PATH Through Life Study

Dietary pattern high in meat, potatoes and soft drinks, low in fruits, vegetables, grains, fish (poor diet) linked to smaller hippocampal volume

(Jacka et al, PLoS Medicine 2015)

## Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND)

Table 1

MIND diet component servings and scoring

Diet component	0	0.5	1
Green leafy* vegetables	$\leq$ 2 servings/wk	>2 to <6/wk	$\geq$ 6 servings/wk
Other vegetables <sup>†</sup>	<5 serving/wk	5 to <7 wk	$\geq 1$ serving/d
Berries <sup>‡</sup>	<1 serving/wk	1/wk	$\geq$ 2 servings/wk
Nuts	<1/mo	1/mo to <5/wk	≥5 servings/wk
Olive oil	Not primary oil		Primary oil used
Butter, margarine	>2 T/d	1–2/d	<1 T/d
Cheese	7 + servings/wk	16/wk	<1 serving/wk
Whole grains	<1 serving/d	1-2/d	≥3 servings/d
Fish (not fried)	Rarely	1-3/mo	≥1 meals/wk
Beans <sup>§</sup>	<1 meal/wk	1-3/wk	>3 meals/wk
Poultry (not fried)¶	<1 meal/wk	1/wk	$\geq$ 2 meals/wk
Red meat and products <sup>#</sup>	7 + meals/wk	4–6/wk	<4 meals/wk
Fast fried foods**	4 + times/wk	1-3/wk	<1 time/wk
Pastries and sweets <sup>††</sup>	7 + servings/wk	5–6/wk	<5 servings/wk
Wine	>1 glass/d or	1/mo6/wk	1 glass/d
	never		-
Total score			15

- Adapted the Medi and Dash diets
- Protective against Alzheimer's pathology
- Uniquely specifies consumption of berries and green leafy vegetables.
- 2 observational studies showed greater adherence to MIND diet reduced risk of developing Alzheimer's disease and less cognitive decline over 10 years.

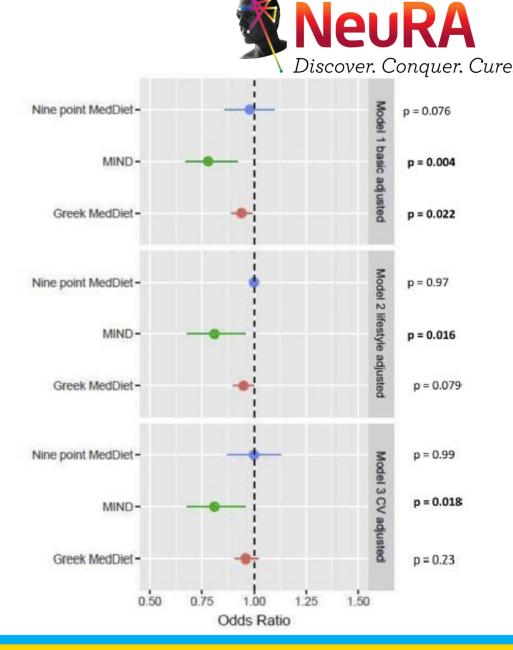

(Morris et al., 2015, Alz Dem)

## MIND Diet – PATH Through Life Project

- 1220 Australians aged 60-64 followed for 12 years
- CSIRO Food Frequency questionnaire
- Coded for MEDI and MIND diets
- MCI and dementia diagnosed at each wave
- MIND Diet (OR = 0.47, 95% CI 0.24-0.91) not MEDI, associated with reduced risk of cognitive impairment and dementia

Hosking, D, Eramudugolla, R., Cherbuin, N, Anstey, KJ, *Alzheimer's* and *Dementia*, 2019

## Smoking

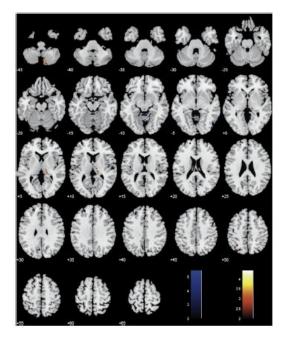

- Meta-analysis 19 prospective studies with at least 12 months of follow-up.
- Mean study age 74 years.
- Current smokers at baseline, relative to never smokers....
  - 1.27 (95% CI: 1.02, 1.60) for any dementia.
  - 1.79 (95% CI: 1.43, 2.23) for Alzheimer's Disease
  - 1.78 (95% CI: 1.28, 2.47) for vascular dementia (Anstey et al Am J Epidemiol 2007).
- Similar results from further meta-analysis (Peters et al BMC Geriatr 2008).
  - Current smokers relative to never or non-smokers....
  - 1.59 (95% CI 1.15, 2.20) for Alzheimer's Disease and
  - 1.35 (95% CI 0.90, 2.02) for vascular dementia

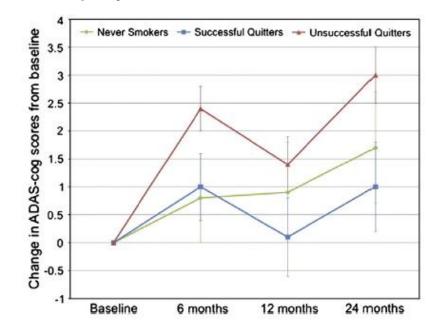

## **Cognitive and brain change in quitters**

Trial of smoking cessation: 36 Never smokers, 48 unsuccessful quitters, 36 successful quitters. Quitters showed no cognitive decline but UQ did. Unsuccessful quitters showed more atrophy

(Almeida et al., 2011, Neuroimage)

## **Blood pressure and incident dementia**

Source	n	Age at baseline	Follow up/yrs	Higher blood pressure associated with increased risk of dementia
Skoog et al 1996	382	70	15	Yes
Lindsay et al 1997	5747	>=65	5	Yes
Launer et al 2000	3703 men	45-68	~22	Yes
Kivipelto et al 2002	1449	44-58	21	Yes
Ninomiya et al 2011	668	65-79	17	Yes

## **Honolulu Asia Aging Study**

Cohort of Japanese American men born between 1900 and 1919 High Systolic blood pressure and incident dementia

**Untreated:** 

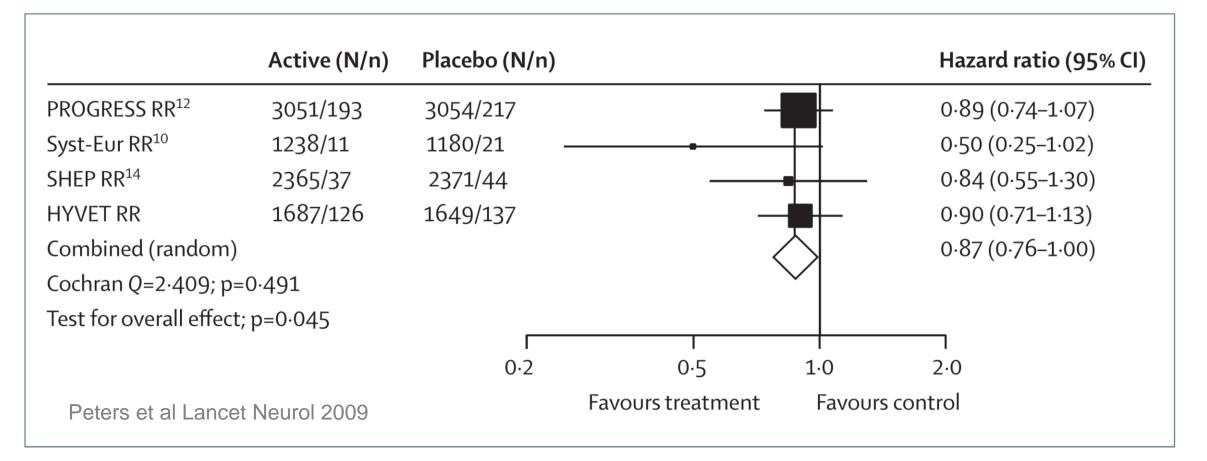

All dementia Odds Ratio (OR) 3.88 (95% Confidence Intervals(CI 1.50-10.02) Alzheimer's Disease OR 1.22 (0.37-4.04) Vascular dementia OR 11.80 (3.52-39.50) Treated: All dementia OR 1.07 (0.53-2.17) Alzheimer's Disease OR 0.65 (0.20-2.15) Vascular dementia OR 1.46 (0.60-3.53)

Launer et al 2000 Neurobiology of Aging

# Blood Pressure lowering trials with antihypertensive medication

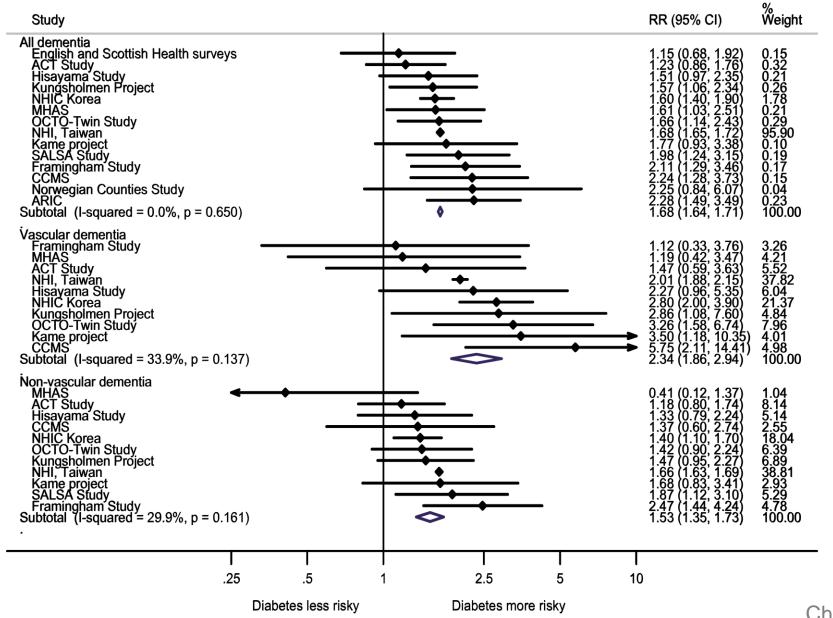

## Systolic blood Pressure Intervention Trial - Memory and Cognition IN Decreased Hypertension (SPRINT-MIND)

- Blood pressure goals <120mmHg versus <140mmHg</li>
- 8563 (91.5%) participants completed at least 1 follow-up cognitive assessment.
- The mean age 67.9 years
- Median follow-up of 5.11 years,
- combined rate of mild cognitive impairment or probable dementia HR, 0.85; 95% CI, 0.74-0.97).

Williamson et al JAMA 2019

# **Diabetes and dementia risk**

14 studies, 2,310,330 individuals women: RR 1.62 [95% CI 1.45–1.80]; men: RR 1.58 [95% CI 1.38–1.81]).

Chatterjee et al Diabetes Care 2016

# But hypoglycaemia is associated with increased risk...

Compared with patients with no hypoglycemia,

- 1 episode......(HR, 1.26; 95% CI, 1.10-1.49);
- 2 episodes..... (HR, 1.80; 95% CI, 1.37-2.36); and
- 3 or more episodes..... (HR, 1.94; 95% CI, 1.42-2.64).

Whitmer et al JAMA 2009

## **Trials of treatments for type 2 diabetes**

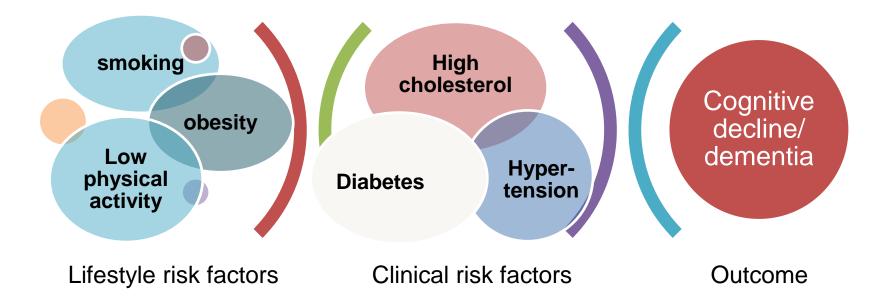

- Cochrane review
- 4 trials reporting cognitive outcomes
- 2 larger trials both comparing standard to intensive blood glucose lowering
- No evidence for treatment reducing risk of dementia
- Intensive treatment was more likely to cause hypoglycaemia

Areosa Satre Cochrane Collaboration et al 2017

# Applicability of the current evidence, ...the real world

Research

Ruth Peters,<sup>1,2,3</sup> Andrew Booth,<sup>4</sup> Kenneth Rockwood,<sup>5</sup> Jean Peters,<sup>4</sup> Catherine D'Este,<sup>6,7</sup> Kaarin J Anstey<sup>1,3</sup>

Objective: to systematically examine the literature addressing clustering or co-occurring modifiable risk factors for incident cognitive decline and dementia within individuals, and to estimate, using meta-analysis, the impact of exposure to one or more modifiable risk factors compared to absence of risk factors on the risk of future cognitive decline and dementia.

## **Risk factor clustering - systematic review**

- Longitudinal studies with an explicit aim to examine the impact of additive or clustered modifiable risk factor burden for combinations of multiple core modifiable dementia risk factors (hypertension or high blood pressure, hypercholesterolemia or high cholesterol, diabetes, high body mass index, smoking, excess alcohol, low physical activity and poor diet).
- Some evidence or clear implication that participants were free of cognitive decline or dementia at baseline assessment.
- Use of formal assessment of cognitive function or dementia or clear implication that formal dementia diagnosis took place.
- Report of cognitive decline or dementia outcomes.

## What has been published?

- >40,000 participants
- High income countries
- Sample size from 322 to 8845
- Two recruited men only
- Follow up from 22 months to >20 years
- Very short follow up (<5 years) n=2</li>
- Short follow up (5-10 years) n=8
- Moderate follow up (10-20 years) n=7
- Long follow up (>20 years) n=5

- Baseline in midlife (40-65 year) n=12
- Baseline in late life (>65 year) n=9
- One study baseline <30 years</li>
- Outcomes
  - dementia (n=10),
  - Alzheimer's Disease (n=5),
  - cognitive function (n=12)

 Higher numbers of risk factors or unhealthy behaviours were associated with increased risk

 Higher numbers of protective factors or health behaviours associated with decreased risk

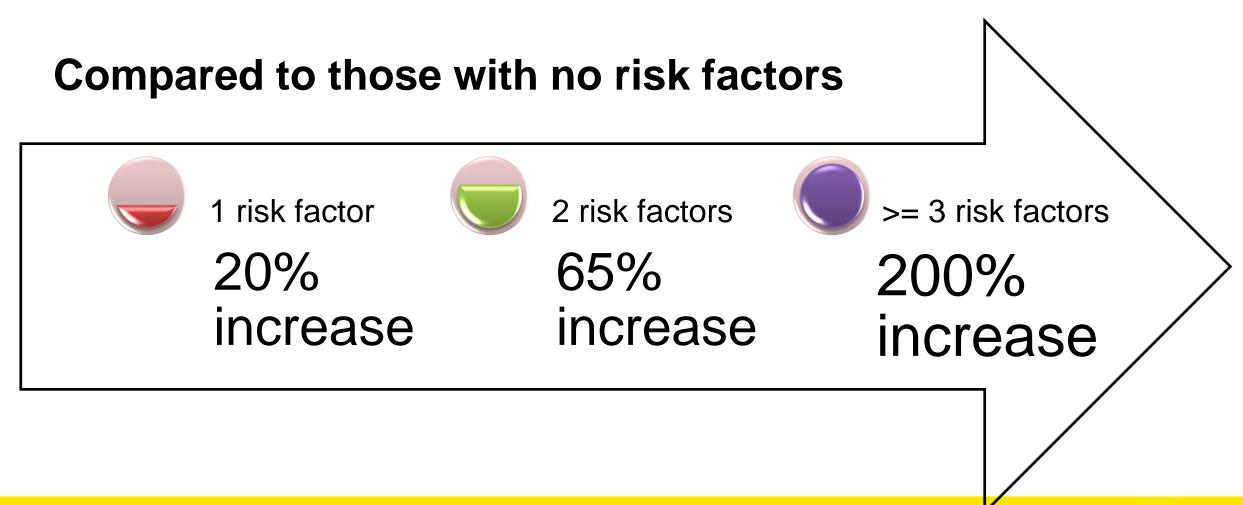

## Meta-analysis, per additional risk factor

## **Future directions**

- Understand whether there are critical windows or ages when risk modification is most effective Better information on targets e.g. for blood pressure, glucose, BMI
- Identify who is at risk and where identify subpopulations, regional differences, sex differences, clinical groups

### What else do we need to achieve this?

- Improved quality of measures to enable results are valid and translatable
- Better cognitive measures that are sensitive to change in younger and midadulthood
- Include cognitive measures as secondary outcomes in trials
- Maintain cohort studies and trial cohorts to gather the long term follow-up data

## What to do now?

- Don'ť smoke
- Meet physical activity guidelines
- Medi or MIND dietary pattern
- Manage vascular risk factors
- Cognitive and social engagement
- Increase population level education
- Conduct more detailed research on risk and outcomes

The IRNDP is a multinational network bringing together researchers who are working to reduce the risk of dementia across the world.
